

Where the estimates fall, by effect size metric

Each point is one specification; labels give the median. Positive favours face-to-face CBT.
Top rows: the published pooled estimates with 95% CI, each placed as its own paper interpreted it.

Distributions run across estimators, instrument rules, inclusion sets and Wright 2005 handling within each metric and data source.
Adjusted differences (Mohr 2012, Luxton 2016) exist only for the reconciled extraction.
Luo 2020 printed -1.73 and read it as eCBT more effective; the 2020 addendum re-read the same number as less change for eCBT (favours face-to-face).
The 2021 corrigendum's -0.92 has the same sign and is placed with the addendum, although its text claims the original conclusions are unchanged.
All published estimates used the standard error of the change score as the SD; see script 01.
